(54) PROJECTION-TYPE LIQUID CRYSTALLINE PROJECTOR.

(57) A projector for synthesizing and projecting an image of three primary colors formed by liquid-crystal light bulbs, wherein deviation in pixels and color shading are improved by correcting errors of the position and angles of mounting the liquid-crystal light bulbs and by eliminating effects on parts caused by the heat of the source of light. For this purpose, there are arranged a plurality of dichroic mirrors, for separating white light into three primary colors, liquid-crystal light bulbs of the three primary

colors, and a dichroic mirror for synthesizing the image. The liquid-crystal light bulb of one color is arranged at a central portion of the housing, and the liquid-crystal light bulbs of the remaining two colors are arranged symmetrically with respect to the first one. Pixels of the two symmetrical liquid-crystal light bulbs are adjusted for their positions relative to each other with respect to pixels of liquid-crystal light bulb in the center.

EP 0 526 653 A1

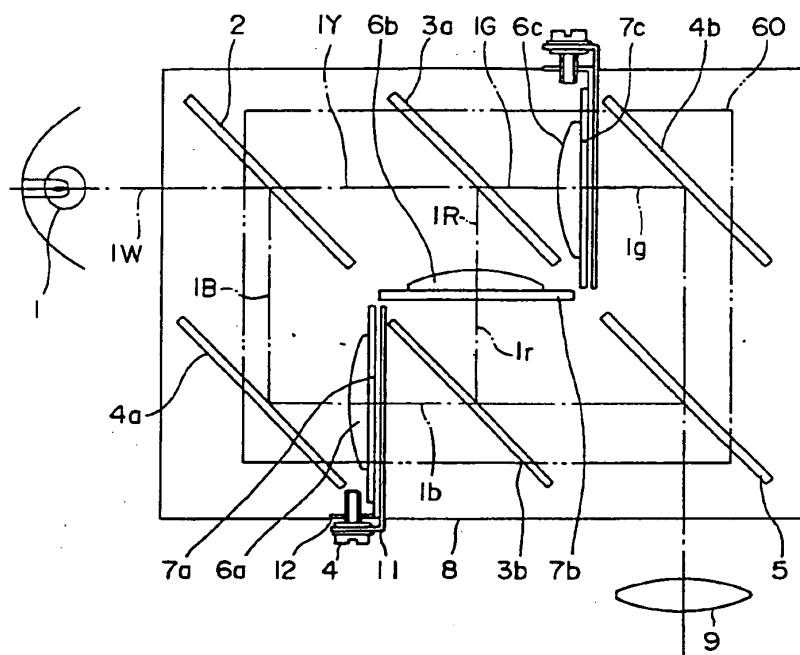

FIG. 1

Technical Field

The present invention relates to a projection type liquid crystal projector for separating white light obtained from for example a video tape into three primary colors, forming images with liquid crystal panels (liquid crystal light bulbs), mixing the images, and projecting an enlarged picture with a projection lens.

Related Art

In a conventional projection type liquid crystal projector as disclosed in Japanese Patent Laid-Open Publication Serial No. SHO 63-247720, white light is separated into three primary colors with dichroic mirrors. With liquid crystal light bulbs, respective images of these colors are formed. Thereafter, with an image mixing mirror, these images are mixed. Next, with a projection lens, the mixed image is enlarged and then projected.

With the above-mentioned projection type liquid crystal projector, pixel positions of the liquid crystal light bulbs, which form blue, green, and red images, cannot be relatively adjusted. In addition, due to deviation of the mounting angles of reflection mirrors disposed in the respective optical paths to the projection lens, the optical axis is deviated. Moreover, due to deviation of the mounting angles of the liquid crystal light bulbs to their optical axes, when the three primary colors are mixed, the resultant image is deviated. The deviations of positions of the liquid crystal light bulbs for blue, green, and red colors to the projection lens result in out-of-focus. As a result, the quality of picture being projected is deteriorated.

To solve these problems, the mounting position and the mounting angle of the liquid crystal light bulb for each color should be adjusted. Nevertheless, in the conventional apparatuses, only a means for moving the mounting positions with eccentric pins or adjustment screws is provided. However, in the apparatus where the positions of the liquid crystal light bulbs are adjusted with the eccentric pins, the rotating direction of the eccentric pin and the moving direction of each liquid crystal light bulb are not uniformly determined. Thus, the adjustment of movement to a desired direction is very difficult to do. In addition, the eccentric pins are not easy to machine. Moreover, E rings, nuts, and so forth are required to secure the eccentric pins. Consequently, the number of parts increases and the assembling work takes a long time, resulting in raising the production cost of the apparatus.

On the other hand, so far, the conventional liquid crystal light bulbs are designed and produced for use in designated colors. In particular, the specifications of the liquid crystal light bulb for

forming a green image whose relative visibility is high are severe. In contrast, the specifications of the liquid crystal light bulb for forming a blue image whose specific visibility is low are comparatively rough. Thus, even if a liquid crystal light bulb which can be satisfactorily used for blue color cannot be used for green color. Therefore, in this situation, this bulb should be treated as a no-good item. Consequently, the yield of these liquid crystal light bulbs are low, thereby raising the production cost.

In addition, the conventional projection type liquid crystal projector is provided with two fans which are an air intake fan and an air exhaust fan as cooling means. With these fans, the interior of the apparatus is cooled down. However, lacking sufficient analization of the air flow paths and so forth, the sphere portion of a light source (metal halide lamp), an UV and IR filter portion, a polarizing plate, a liquid crystal panel, electric parts for an exhaust opening, electric devices, and so forth are not satisfactorily cooled down. Thus, these constructional parts are heated to temperatures close to their limit values. On the other hand, there are demands of brighter projectors and low-noise ones in the marketplace. However, the conventional cooling means cannot satisfy such demands. Unless the above-mentioned constructional parts are satisfactorily cooled down, problems such as deteriorating image quality and decreasing service life would take place. Although the increase of the size and weight of the projector is not permitted at all, the conventional techniques have not satisfy such demands. In particular, the light source is not satisfactorily cooled down.

An object of the present invention is to enable a projection type liquid crystal projector to clearly display images and to provide a projector which is small in size, easy to adjust, and high in reliability. Another object of the present invention is to provide a projection type liquid crystal projector having high cooling efficiency by arrangement of relevant constructional parts, small and thin construction, and excellent properties with respect to operability, durability, and maintainability. A further another object of the present invention is to provide a projection type liquid crystal projector having a projection light source which is free of deteriorations of image quality such as deviations of intensity, colors, and picture elements (pixels) and a lighting unit having a long service life as the light source.

Disclosure of the Invention

The projection type liquid crystal projector according to the present invention comprises optical means, comprising a light source, a plurality of

dichroic mirrors for separating white light emitted by the light source into blue, green, and red colors of rays, respective liquid crystal light bulbs for forming images of the blue, green, and red colors of rays so as to form optical paths, and a projection lens, wherein the optical means is characterized in that at a center portion of a chassis made of members with rigidity a first color type bulb of the liquid crystal light bulbs for forming the red, green, and red colors of rays, second and third color type bulbs of the liquid crystal light bulbs being disposed at positions point-symmetrical to the first color bulb, and wherein the projection type liquid crystal projector further comprises an adjustment mechanism for mutually matching pixels of the second and third color bulbs with those of the first color bulb.

Thus, the positions and angles of the liquid crystal light bulbs can be easily and securely adjusted. In addition, the deviations of color images and out-of-focus can be prevented. Consequently, the quality of the projected images can be improved.

Part of the adjustment mechanism has notches at opposed positions of a plurality of members slidably provided each other. Into these notches, a tool such as a screwdriver can be inserted so as to perform an adjustment work.

The chassis on which the liquid crystal light bulbs, mirrors, and so forth are fixed is made of a metal plate. The periphery of the chassis is formed by bending work or drawing work.

In addition, the projection type liquid crystal projector according to the present invention comprises a white lamp, dichroic mirrors for separating light of the white lamp into rays of three colors of red, green, and blue, and liquid crystal light bulbs for transmitting the rays of three colors and for forming images, wherein a blue color type bulb for forming a blue image of the liquid crystal light bulbs has the same construction as a green color type bulb thereof so as to have compatibility each other.

Further, the projection type liquid crystal projector according to the present invention comprises a case nearly in a rectangular parallelepiped shape, a base plate disposed in the case, a lamp housing unit having a projection light source, an optical unit, comprising image forming liquid crystal light bulbs, light mixing and separating mirrors, dichroic mirrors, prepolarizers, and a projection lens, the lamp housing unit and the optical unit being disposed on the base plate so that a main optical path and the outer shape become a plane L shape, the projection lens facing a window of the front of the case, one end of the lamp housing unit facing a window of a lamp house cover on a side of the case and the other an air exhaust opening in the rear of the

case, a power unit and a lamp stabilizer disposed at a space surrounded by the plane L shape portion, the front and the side of the case, an air intake regulating plate disposed below the liquid crystal light bulbs, an air intake fan disposed below the air intake regulating plate, a video board disposed between a side of the case and the light guide unit, a liquid crystal drive board unit disposed midway between the top of the case and the top of the light guide unit, an air exhaust fan disposed midway between the air exhaust opening in the rear of the case and the lamp housing unit, and a lamp fan disposed in the front of a light emit surface of the lamp housing unit.

Furthermore, as cooling means of the light source, the air exhaust fan disposed adjacent to the lamp house and a small blowing lamp fan disposed adjacent to a reflector opening portion of the lamp reflector are provided.

Modes for Carrying out the Invention	
With reference to the accompanying drawings, the present invention will be described in detail.	
Fig. 1 is a schematic plan view showing an optical system of an embodiment according to the present invention. Reference numeral 1 is a light source. Reference numeral 2 is a blue dichroic mirror which reflects blue color of light and allows other colors of light to pass through (hereinafter, this mirror is referred to as B.D.M.). Reference numerals 3a and 3b are red dichroic mirrors which reflects red of light and allows other colors of light to pass through (hereinafter these mirrors are referred to as R.D.M.). Reference numerals 4a and 4b are reflection mirrors. Reference numeral 5 is a dichroic mirror which allows green of light to pass through, reflects other colors of light, and mixes red, green, and blue colors of light (hereinafter, this mirror is referred to as a mixing mirror). Reference numerals 6a, 6b, and 6c are condenser lenses. Reference numeral 7a is a liquid crystal light bulb for forming an image of blue color of light. Likewise, reference numerals 7b and 7c are liquid crystal light bulbs for forming images of red and green colors of light, respectively. Reference numeral 8 is a chassis for holding and fixing the above-mentioned parts and so forth. Reference numeral 9 is a projection lens. The above-mentioned parts 2, 3a, 3b, 4a, 4b, 5, 6a, 6b, 6c, 7a, 7b, 7c, and so forth, which are fixed and held with the chassis 8, construct an optical means.	
Now, the traveling of light in the optical means will be described. The light source 1 generates white light 1w. The B.D.M. 2 reflects only a ray	

Modes for Carrying out the Invention

With reference to the accompanying drawings, the present invention will be described in detail.

Fig. 1 is a schematic plan view showing an optical system of an embodiment according to the present invention. Reference numeral 1 is a light source. Reference numeral 2 is a blue dichroic mirror which reflects blue color of light and allows other colors of light to pass through (hereinafter, this mirror is referred to as B.D.M.). Reference numerals 3a and 3b are red dichroic mirrors which reflects red of light and allows other colors of light to pass through (hereinafter these mirrors are referred to as R.D.M.). Reference numerals 4a and 4b are reflection mirrors. Reference numeral 5 is a dichroic mirror which allows green of light to pass through, reflects other colors of light, and mixes red, green, and blue colors of light (hereinafter, this mirror is referred to as a mixing mirror). Reference numerals 6a, 6b, and 6c are condenser lenses. Reference numeral 7a is a liquid crystal light bulb for forming an image of blue color of light. Likewise, reference numerals 7b and 7c are liquid crystal light bulbs for forming images of red and green colors of light, respectively. Reference numeral 8 is a chassis for holding and fixing the above-mentioned parts and so forth. Reference numeral 9 is a projection lens. The above-mentioned parts 2, 3a, 3b, 4a, 4b, 5, 6a, 6b, 6c, 7a, 7b, 7c, and so forth, which are fixed and held with the chassis 8, construct an optical means.

Now, the traveling of light in the optical means will be described. The light source 1 generates white light 1w. The B.D.M. 2 reflects only a ray

having a wavelength range of blue, namely blue color 1b of light 1w and allows other rays of light having other wavelength range (yellow color of light) to pass through. The R.D.M. 3a only reflects only a ray having a wavelength range of red 1R of the light 1Y and allows the remaining green ray 1G to pass through. The ray 1G is condensed with the condenser lens 6c and then an image is formed thereby as a ray 1g. The ray 1g is reflected with the reflection mirror 4b. Thereafter, the ray 1g passes through the mixing mirror 5. Then, the ray 1g is projected onto a screen with the projection lens 9. The blue ray 1B is reflected with the reflection mirror 4a. Then, the blue ray 1B passes through the condenser lens 6a. Thereafter, the liquid crystal light bulb 7a forms an image as a ray 1b. Then, the ray 1b passes through the R.D.M. 3b and comes to the mixing mirror 5. Likewise, the red ray 1R passes through the condenser lens 6b and comes to the liquid crystal light bulb 7b. Then, the liquid crystal light bulb 7b forms an image as a ray 1r. The ray 1r is reflected with the R.D.M. 3b and then comes to the mixing mirror 5. The mixing mirror 5 reflects the rays 1b and 1r and mixes the rays of three primary colors 1g, 1b, and 1r as a displayable picture. The projection lens 9 projects the picture on the screen.

It should be appreciated that the liquid crystal light bulb 7b disposed in the middle position of the optical means can be used for the red ray of light, the liquid crystal light bulb 7a for green ray of light, and the liquid crystal light bulb 7c for blue ray of light. Since each dichroic mirror disposed in the optical path has an inclination to the optical axis, different optical paths take place. Thus, in this construction, since green ray having high relative visibility is not used, astigmatism and thereby unsharpness can be prevented.

To clearly display a picture, it is necessary to mix the rays 1g, 1b, and 1r in such a way that their mutual positions do not deviate. Thus, the mutual pixel positions of the liquid crystal light bulbs 7a, 7b, and 7c should be accurately matched each other. In addition, these pixel positions should be precisely matched with the back-focus position of the projection lens 9. Fig. 4 is a perspective view showing an example of a fixing and adjusting mechanism of the liquid crystal light bulb 7a. As shown in the figure, the liquid crystal light bulb 7a is mounted on a circuit board 10. The board 10 is fixed to Z shaped bend portions (four positions) disposed on a fixing plate 11 with screws 13. One side of the fixing plate 11 is positioned with an oval hole 11b and a dowel 12a formed on a fixing plate 12. In addition, a screw 14 pivoted with a bend portion 12b on the fixing plate 12 is connected to a bend portion 11c of the fixing plate 11. Thus, the fixing plate 11 is laterally slidably supported with

the fixing plate 12. The fixing plate 11 and the fixing plate 12 are fixed with screws 15 (two positions) through spring washers 16. In the center of the fixing plate 12, an opening portion 12c is formed. About the center of the opening portion 12c, arc shape holes 12d (three positions) are formed as outer concentric circles. Dowels 19a (three positions) formed on the fixing plate 19 are positioned and guided to the holes 12d. In addition, an eccentric pin 17 connected to an oval hole 12e formed on the fixing plate 12 and rotatably caulked with a washer 18 is pivotally supported with a hole 19b formed on the fixing plate 19. Thus, the rotation of the fixing plate 12 can be adjusted by the amount of eccentricity for which the eccentric pin 17 is rotated. In addition, a washer 20 connected to (the rear of) a dowel on the fixing plate 19 is fixed to a screw hole 12f formed on the fixing plate 12 with a screw 22 which pierces a deformed hole 19d formed on the fixing plate 19 through a spring washer 21. Thus, the fixing plate 12 and the fixing plate 19 can be fixed. A notch 19f at a lower portion of an opening portion 19e formed in the center of the fixing plate 19 is connected to a dowel 23a formed on a fixing plate 23. Thus, one side of the fixing plate 19 is positioned and guided to the fixing plate 23. On the other hand, a screw 24 pivotally supported with a bend portion 19g of the fixing plate 19 is connected to a screw hole 23c formed on a bend portion 23b over the fixing plate 23. Thus, the fixing plate 19 is positioned and guided to the fixing plate 23 so that the longitudinal position of the liquid crystal light bulb 7a can be adjusted. The fixing plate 19 is fixed in such a way that screws 25 (two positions) which pierce respective oval holes 23d (two positions) formed on the fixing plate 23 are connected to screw holes 19i (two positions) formed on the fixing plate 19 through respective spring washers 26 (two positions).

In the above-mentioned construction, by moving pixels of the liquid crystal light bulb 7a in the horizontal, vertical, and rotational directions, these pixels can be matched with those of the liquid crystal light bulb 7b. In addition, to more securely fix the liquid crystal light bulb 7a, screws 27 (two positions) which pierce respective oval holes 11d (two positions) formed on the fixing plate 11, respective oval holes 12g (two positions) formed on the fixing plate 12, respective oval holes 19 formed on the fixing plate 19 (two positions) are connected to respective screw holes 23e (two positions) formed on the fixing plate 23 through respective spring washers 28 (two positions). By controlling the tightening torque of the screws 27, they allow the fixing plate 11, the fixing plate 12, and the fixing plate 19 to be resiliently fixed to the fixing plate 23 by the use of a resilient force of the spring

washers 28. Thus, since the fixing plates 11, 12, 19, and 23 can be temporarily fixed each other by frictional forces, the mutual displacements thereof can be prevented during an adjustment work. After the adjustment mechanism has been mounted, the screws 27 are present at unaccessible positions (see Fig. 2). Thus, the permanent tightening work can be omitted. Likewise, since the spring washers 16, 21, and 26 allow the position of the liquid crystal light bulb 7a to be adjusted, when the above-mentioned screws and so forth are tightened, the resilient forces of these spring washers 16, 21, and 26 prevent the mechanism from being displaced.

In the above-mentioned adjustment mechanism, the fixing plate 11, the fixing plate 12, the fixing plate 19, and the fixing plate 23 have the same center dimensions in their outer shapes (in left and right directions). Thus, by assembling these fixing plates 11, 12, 19, and 23 in such a way that these outer shapes are matched, a position accuracy without a remarkable deviation to the desired center can be obtained. In addition, by providing a means for forming a gap between each connecting surface of the fixing plates 11, 12, 19, and 23, the gap prevents warping, distortion and so forth of parts from badly affecting the liquid crystal light bulb 7a.

Next, a mechanism for fixing and adjusting the position of the liquid crystal light bulb 7a on the chassis 8 will be described in detail. Fig. 2 is a schematic assembly sectional view showing a part of the adjustment mechanism in the above-mentioned construction. Fig. 3 is a schematic assembly plan view of Fig. 2. As shown in Figs. 1, 2, and 4, an upper fixing auxiliary plate 29 is pivotally guided to a bend portion 23b over the fixing plate 23 in such a way that a dowel 23f formed on the bend portion 23b can be rotated. In addition, the upper fixing auxiliary plate 29 is connected to an eccentric pin 30 which is rotatably caulked to the bend portion 23b. Thereafter, the upper fixing auxiliary plate 29 is temporarily fixed to the bend portion 23b with screws 31 (two positions). The upper fixing auxiliary plate 29 is temporarily fixed to an upper chassis 8a with screws 32 through screw holes 29a (two positions) formed on the upper fixing auxiliary plate 29. A dowel 29c formed on the upper fixing auxiliary plate 29 is connected to an oval hole (not shown in the figure) on the upper chassis plate 8a. In addition, a screw 33 pivotally held with a bend portion 8c formed on the upper chassis plate 8a is connected to a bend portion formed on the upper fixing auxiliary plate 29 with a screw. Thus, the mechanism can adjust the focus direction of the liquid crystal light bulb 7a. Since the eccentric pin 30 can be adjusted from an opening portion (not shown in the figure) formed on

the upper chassis plate 8a. Thus, the amount of angular deviation in the direction perpendicular to the optical axis of the liquid crystal light bulb 7a can be adjusted. After the above-mentioned two adjustment works are completed, by permanently tightening the screws 31 and 32, the upper direction of the adjustment mechanism is fixed.

Next, with reference to Figs. 2, 4, and 5 (Fig. 5 is a perspective view seen from an arrow mark of Fig. 4), the adjustment and fixing of the adjustment mechanism in the lower direction will be described. Dowels 8d (two positions) and an eccentric pin 35 are rotatably caulked to a lower chassis plate 8b. The dowels 8d and the eccentric pin 35 allow the lower fixing auxiliary plate 34 to be positioned. A bend portion 23g formed on the fixing plate 23 is guided with a dowel 34a and mounted to the auxiliary plate 34. With screws 36 (two positions), the lower fixing auxiliary plate 34 and the bend portion 23g are temporarily fixed. In addition, with screws 37 (two positions), the lower fixing auxiliary plate 34 and the lower chassis plate 8b are temporarily fixed. The focus adjustment in the lower direction is performed in accordance with the amount of eccentricity of the eccentric pin 35. Thereafter, the screws 37 (two positions) are permanently tightened. After the angle adjustment in the plane direction to the upper optical axis is completed, the screws 36 are permanently tightened along with the screws 31. Obviously, the plane positions of the dowels 23f and 34a have been matched each other in the reference dimensions. In addition, screwdriver access holes for tightening the screws 36 and 37 and rotating the eccentric pin 35 are formed on the bend portion 23b of the fixing plate 23 and the upper fixing auxiliary plate 29 (this part will be described later in detail).

Next, as shown in Fig. 3, pixels in the horizontal direction can be adjusted from a side direction of the chassis with a screwdriver because the screw 14 is disposed at the opening portion formed on a side of the chassis 8. As described above, the adjustment of deviation of pixels in the vertical, horizontal, and rotational directions is performed in the adjustment mechanism. The deviation of plane angle between the focus direction (including the vertical direction) and the direction of the optical axis is adjusted with fixing portions for fixing the adjustment mechanism and the chassis.

The liquid crystal light bulb 7c is disposed in such a way that it is symmetrical to the liquid crystal light bulb 7a.

Next, a supporting and fixing mechanism of the liquid crystal light bulb 7b disposed at a center portion of the chassis 8 will be described. When the liquid crystal light bulb 7b can be disposed within the depth of focus of the projection lens 9, the unsharpness of pixels projected on the screen

does not affect the visibility of human eyes. However, in the cases of the mount construction of the liquid crystal light bulb 7b and the construction of this embodiment, where the chassis 8 is made of metal plates and so forth, due to the overall effects of the tolerance involved in the constructional elements and the machining tolerance, the position of the liquid crystal light bulb 7b is not sometimes placed in the range of the above-mentioned allowable depth of focus. Thus, the adjustment mechanism for allowing the focus direction to be adjusted is required. An example of this mechanism will be described with reference to Fig. 6. As shown in Fig. 6, in an adjustment mechanism for adjusting the upper direction of the liquid crystal light bulb 7b, the bulb 7b is mounted on a circuit board 41 which is fixed to convex portions (four positions) formed on a fixing plate 42 with screws 40 (four positions). In addition, a lower fixing auxiliary plate 44 is positioned and guided to the lower chassis plate 8b with dowels 8e (two positions) formed on the lower chassis plate 8b and an eccentric pin 43 rotatably caulked to the lower chassis plate 8b. The lower fixing auxiliary plate 44 is temporarily fixed with screws 49 (two positions). A dowel 44a provided on the lower fixing auxiliary plate 44 is rotatably connected to a hole 42c formed in the center of a bend portion 42b formed on the fixing plate 42. Thereafter, the fixing plate 42 and the fixing auxiliary plate 44 are temporarily fixed with screws 45 (two positions). The fixing auxiliary plate 47 which is pivoted with a dower 42e at a center portion of a bend portion 42d formed over the fixing plate 42 and which is positioned and guided with an eccentric pin 46 rotatably caulked to a hole 42f is temporarily fixed with a screw 50. Dowels 47a (two positions) disposed on the upper fixing auxiliary plate 47 and an eccentric pin 48 rotatably caulked are positioned and guided to oval holes 8f (two positions) and 8g (one position) formed on the upper chassis plate 8a. Then, the upper fixing auxiliary plate 47 is temporarily fixed to the upper chassis plate 8a with screws 51 (three positions). Of course, the upper chassis plate 8a has screwdriver access holes (see Fig. 7) so that screws and so forth mounted below the upper chassis plate 8a can be mounted and removed. In the focus adjustment work, the upper direction of the focus is adjusted with the amount of eccentricity of the eccentric pin 48. Likewise, the lower direction of the focus is adjusted with the amount of eccentricity of the eccentric pin 43. In addition, the angular deviation in the plane direction to the optical axis is adjusted with the amount of eccentricity of the eccentric pin 46. After the above-mentioned adjustment work is completed, the screws 49, 45, 50, and 51 are permanently tightened so as to securely fix the adjustment mecha-

nism. Thus, all the adjustment work of this mechanism can be performed. If the position of the liquid crystal light bulb 7b were in the allowable range of depth of focus of the backfocus of the projection lens by means of simplified mount construction of the liquid crystal light bulb 7b or improved machining accuracy thereof, the above-mentioned adjustment mechanism could be omitted.

As described above, since the angular deviation in the plane direction to the optical axis is adjusted only in the direction of the chassis plate 8a, the adjustment work and the mechanism thereof are simplified. In addition, by horizontally forming a 90° bend portion (not shown in the figure) at an end of each of the fixing plate 23 and the fixing plate 42, along with the reinforcement of their fixing plates and the improvement of the surface accuracy thereof, disturbing light can be effectively prevented. In addition, when the bend portions 23b, 23g, 42b, and 42d formed on the fixing plate 23 and the fixing plate 42 fixed between the chassis plates 8a and 8b are fixed with screws, errors of the bend angles of the bend portions become bending moments. These bending moments are applied to these chassis. To suppress this bad influence applied to the liquid crystal light bulbs 7a and 7b and the deviation of the adjustment mechanism, at the base of each bend portion, an opening portion is formed so as to reduce the amount of bending.

In particular, since the chassis plates 8a and 8b, the fixing plates 11, 12, 19, 23, and 42, the upper fixing auxiliary plates 29 and 47, the lower fixing auxiliary plates 34, and 44, and so forth are made of the same material such as steel parts, they have the same coefficient of linear expansion. Thus, the parts of the adjustment mechanism uniquely expand and shrink.

In addition, the position accuracy of the positioning holes and dowels on the chassis 8 for use with the fixing mechanisms of the mirrors, the liquid crystal light bulbs is of the order of approximately 10 microns. Moreover, a simple construction is used in such a way that the liquid crystal light bulbs are directly fixed to the fixing plate 23. Further, the allowable depth of focus of the backfocus of the projection lens 9 can be suppressed to approximately 200 microns or below. Furthermore, when the size of the liquid crystal light bulbs is of approximately 3 inches and the number of pixels thereof is of the order of approximately 100,000, a construction which does not require the adjustment in the focus direction can be satisfactorily accomplished. In addition, when the amount of deviation of pixels in the horizontal and vertical directions is of approximately 1/2 to 2/3 times the amount of the related art, a construction which does not require the matching of pixels can be also accomplished.

As described above, according to the above-mentioned construction, with reference to pixels of a first liquid crystal light bulb disposed in the center of the chassis, pixels of a second liquid crystal light bulb disposed point-symmetrically to the first liquid crystal light bulb are adjusted. Thus, the mechanism for fixing the liquid crystal light bulb disposed in the center of the chassis can be constructed simply and in a small size. Therefore, an optical system with a short optical path can be designed. Consequently, this construction can contribute to reducing the size of the optical system, namely, the size of the final product.

In addition, since the position adjustment work of the liquid crystal light bulb disposed in the center of the chassis can be performed from the top thereof, the disability of adjustment from the side thereof due to the constructional restriction can be compensated. Moreover, since the adjustment work of the liquid crystal light bulbs disposed point-symmetrically to another bulb is available from the top and the side, the number of work steps can be reduced. Furthermore, since the adjustment work from the side can be performed by using a simple adjustment jig in the final product state where the optical apparatus is mounted in a real machine, the adjustment quality is improved.

Since the shapes of the parts of the fixing and adjustment mechanism of the liquid crystal light bulbs disposed point-symmetrically can be formed symmetrically to those of the bulb disposed in the center of the chassis, the number of design and machining steps can be reduced.

In addition, since the constructional parts of the adjustment mechanism can be assembled in accordance with their outer shapes, the assembled adjustment mechanism can have the nearly designed accuracy. Thus, since the adjustment work can be easily estimated and the number of working steps can be reduced. Moreover, by the accomplishment of the construction in a small size, the projection lens and the mirrors can have high cost performance. In addition, the construction in the small size contributes to decreasing the size of the final product and reducing the costs of the apparatus and the final product.

Since the liquid crystal light bulbs and polarizing plates (not shown in the figure) are exposed to strong light, they become hot. To maintain the performance of these parts, a forced cooling mechanism is required. To accomplish this mechanism, a fan 60 for drawing outer air is disposed below the chassis 8b (see Fig. 1). To equally cool down the liquid crystal light bulbs and the polarizing plates, the center portion of the fan 60 should be disposed in the vicinity of the liquid crystal light bulb 7b disposed at the center portion of the chassis 8b. However, since a motor is disposed at the

center portion of the fan, the amount of air blow is low. To improve the air blow capacity, the amount of air blow is adjusted by using a regulating plate. However, in the present invention, since the fixing mechanism of the liquid crystal light bulb 7b disposed at the center portion of the chassis is simplified, the fluid resistance is decreased. Thus, without a particular regulating means, the fixing mechanism of the liquid crystal light bulb 7b contributes to the improvement of the cooling efficiency.

Since the constructional parts of the optical apparatus are made of the same material, they equally expand and shrink against temperature changes. Thus, the deviation of positions in the adjustment mechanism can be suppressed. In other words, since the deviation of pixels between the liquid crystal light bulbs are suppressed, the quality and accuracy of the pictures can be improved.

As described in the last part of the above-mentioned embodiment, when light incident to the projection lens 9 causes red and green rays to be reflected with a mixing mirror, the adjustment accuracy of matching pixels of the liquid crystal light bulb 7b for red with those of the liquid crystal light bulb 7a for green can be improved in a relatively small number of adjustment steps. When light enters the projection lens in the inverse order of the optical paths, since red and green rays are reflected on the same surface of the mixing mirror 5, the amount of deviation of the optical axis due to the deviation of position of the mixing mirror 5 for the red ray is the same as that of the green ray. Thus, the amount of deviation of the red and green rays is equal to the amount of deviation due to the deviation of position of the R.D.M. 3b and the amount of deviation between the mutual positions of the liquid crystal light bulbs 7a and 7b. Consequently, the amount of deviation becomes small. In addition, since the pixels of the liquid crystal light bulb 7a can be stably matched with those of the liquid crystal light bulb 7b, they can be adjusted in a small number of adjustment steps. On the other hand, with respect to the blue ray, in addition to the amount of deviation of the optical axis due to the deviation of position of the mixing mirror 5, the deviation of the optical axis due to the deviation of position of the reflection mirror 4b and the amount of deviation between the mutual positions of the liquid crystal light bulb 7b and 7c are added. Thus, the number of adjustment steps increases in accordance with the amount of deviation. However, since the relative visibility of the blue ray is low, even if there is still a minor error to adjust, the error does not affect the picture quality.

In addition to setting the sizes of the liquid crystal light bulbs, the number of pixels, and the allowable depth of focus of the projection lens, when the improvement of the machining accuracy

of parts and the simplification of the fixing mechanisms of the liquid crystal light bulbs are accomplished, the construction which does not require the adjustment of the focus direction with respect to the position of the liquid crystal light bulb disposed at the center portion of the chassis can be accomplished. Alternatively, the construction which requires only the adjustment for placing the liquid crystal light bulb to a position perpendicular to the optical axis can be accomplished. Thus, the mechanism can be further simplified. In addition, the construction which does not require the adjustment of matching pixels can be accomplished. Consequently, such a construction allows the cost reduction including the reduction of the number of production steps and parts. Thus, the present invention contributes to reducing the cost of products which were expensive.

Figs. 7 and 9 show a practical example of an adjustment and operation mechanism which can be adjusted with a screwdriver. These figures present a light bulb mounting surface where the liquid crystal light bulb is mounted and adjustment positions of the light bulb.

As shown in Fig. 7 which presents an embodiment of the adjustment and operation mechanism, a liquid crystal light bulb is mounted on a light bulb board 50. The light bulb board 50 is fixed to a light bulb fixing plate with screws. A dowel 51a of the light bulb fixing plate 51 is rotatably guided to a lower adjustment plate 52. A dowel 51b of the light bulb fixing plate 51 is rotatably guided to an upper adjustment plate 53. The light bulb fixing plate 51 is fixed to the lower adjustment plate 52 with screws. The lower adjustment plate 52 is slidably connected to the lower light guide 54 with oval holes 52a and dowels 54a formed thereon. The lower adjustment plate 52 is fixed to the lower light guide 54 with screws. The upper adjustment plate 53 is slidably connected to an upper light guide 55 with an oval hole 53a and a dowel 55a. The upper adjustment plate 53 is connected to the upper light guide 55 with screws. The lower light guide 54 and the upper light guide 55 are spaced apart with a column 56. The lower light guide 54 and the upper light guide 55 are fixed to the column 56 with screws.

The upper adjustment plate 53 has a notch 53b. The upper light guide 55 opposed to the notch 53b has a hole 55b which is the same shape as the notch 53b. A space formed with the notch 53b and the hole 55b has a shape where the tip of the screwdriver D can be inserted regardless of the position of the upper adjustment plate 53 in its allowable slideable range. Fig. 8 shows the detail of the shapes of the notch and hole. By loosening a screw which fixes the upper adjustment plate 53 and the upper light guide 55 and rotating the tip of

screwdriver inserted into the space between the notch 53b and the hole 55b, the upper adjustment plate 53 is guided and slid with the oval hole 53a and the dowel 55a. Thus, an upper portion of the light bulb fixing plate 51 rotatably guided with the upper adjustment plate 53 approaches to or goes away from the projection lens 57. The direction in which the light bulb fixing plate 51 moves just accords with the direction in which the screwdriver D rotates.

Likewise, by loosening a screw which fixes the lower light guide 54 and the lower adjustment plate 52 and rotating the tip of the screwdriver inserted into the space between a notch 52b and a hole 54b, the lower adjustment plate 52 is guided and slid with the oval hole 52a and the dowel 54a. Thus, a lower portion of the light bulb fixing plate 51 rotatably guided with the lower adjustment plate 52 approaches to and goes away from the projection lens 57.

The light bulb fixing plate 51 has a notch 51c. The lower adjustment plate 52 opposed to the notch 51c has a hole 52c which has the same shape as the notch 51c. By loosening a screw which fixes the light bulb fixing plate 51 and the lower adjustment plate 52 and rotating the tip of the screwdriver inserted into the space between the notch 51c and the hole 52c, the light bulb fixing plate 51 rotates about a line which passes through the dowel 51a and the dowel 51b. At this point, the direction in which the driver rotates just accords with the direction in which the light bulb fixing plate 51 rotates.

In the above-mentioned construction, only by removing the screws which fix the upper adjustment plate 53 and the light bulb fixing plate 51, the adjustment mechanism can be dismounted from the light guide. Thus, the workability in the assembling process and after-service is very high.

Fig. 9 shows an example where the combination of the above-mentioned notch and hole is used to an alignment adjustment mechanism of a three-plate projection type liquid crystal projector. In the three-plate liquid crystal projection apparatus, to match the apparent positions of the three R, G, and B liquid crystal panels, the apparent positions of at least two liquid crystal panels should be adjusted in the horizontal, rotational, and vertical directions. In an example shown in Fig. 9, a horizontal adjustment plate 58 has a plurality of notches so as to widen the adjustment range. By forming holes with the same shape as the notches on the rotation adjustment plate 59, adjustment portions can be disposed at any positions of the rotation adjustment plate 59 rather than the notches disposed on the periphery thereof. Thus, the degree of freedom can be improved in designing the rotation adjustment plate 59. In Fig. 9, reference numeral 60 is a

vertical adjustment plate.

Consequently, in the above-mentioned construction, the position of the light bulb can be adjusted with a minimum number of parts. In addition, since the tip of screwdriver fits to the space between the notch and the hole, the screwdriver does not fall during the adjustment work. Moreover, since the direction in which the screwdriver rotates just accords with the direction in which the light bulb moves, the adjustment work can be easily performed.

By applying the above-mentioned adjustment and operation mechanism to the matching of pixels of the liquid crystal light bulbs 7a, 7b, and 7c, the mechanism can be simplified.

As described above, in the projection type liquid crystal projector, light of a white light source is separated into rays of three colors of red, green, and blue with dichroic mirrors. Thereafter, the rays of these colors enter liquid crystal panels. Next, these rays are mixed by dichroic mirrors. Then, the mixed ray is projected onto a screen by a projection lens. Thus, if the accuracies of the positions and angles of the dichroic mirror (B.D.M.) and the reflection mirrors 4a and 4b are low, the optical axis of each color deviates and irregular colors take place in the picture (hereinafter, this situation is referred to as unevenness of colors). Moreover, in this situation, images projected from the panels are deviated (hereinafter, this situation is referred to as deviation of pixels).

In this embodiment, since the lower chassis plate 8b, which mounts the dichroic mirrors, reflection mirrors, and so forth, is made of a metal plate, the production cost of the lower chassis plate 8b is low. In addition, the accuracy of the metal mold is very high. Thus, the lower chassis plate 8b can be quantitatively produced with high accuracies of positions and angles of part mounting holes. In other words, since there is no deviation of each color, the optical system units free of unevenness of colors and deviation of pixels can be quantitatively produced. The design of the units can be easily changed by slightly modifying the design of the metal mold.

If a liquid crystal projector were constructed in such a way that the optical system unit, which mounts the dichroic mirrors, reflection mirrors, and so forth, is fixed to an outer case with screws, the lower chassis plate would be exposed to an excessive force. Thus, the positions and angles of the dichroic mirrors, reflection mirrors, and so forth, which are mounted on the lower chassis plate, would deviate. Thereby, the optical axes in the optical system unit would deviate, resulting in occurrences of unevenness of colors and deviation of pixels. However, in this embodiment, the periphery of the lower chassis plate is processed by a bend-

ing work, the adjacent portion being processed by a spot welding work 8i, the resultant plate being formed in a box shape by a drawing work or the like. Thus, the strength of the lower chassis plate can be maintained, thereby preventing the positions and angles of the dichroic mirrors, reflection mirrors, and so forth from deviating. Consequently, the strength of the optical system unit can be maintained, so that unevenness of colors and deviation of pixels can be prevented. When the lower chassis plate is fixed to the outer case and other board at three points in the vicinity of the ray mixing portion or in the vicinity of the separating portion, the force applied to the lower chassis plate can be decreased. This is because there are many vent openings on the cooling upper and lower chassis plates in the vicinity of the liquid crystal light bulb. Thus, the strength of these portions is high. When the lower chassis plate is fixed to a portion with a high strength in the region from the lamp to the liquid crystal light bulb or the region from the liquid crystal light bulb to the reflection lens, the flatness of the lower chassis plate can be kept. On the other hand, the mounting portion of the projection lens is not in a box shape. Thus, the strength of this portion is low. However, by placing the upper chassis plate 8a on the lower chassis plate in the same box shape as the upper chassis plate, the relevant strength can be kept. As described above, this embodiment is suitable for quantitatively producing liquid crystal video projectors which can project beautiful pictures.

Next, with reference to Figs. 10 and 11, an embodiment of the liquid crystal video projector will be described. Fig. 10 is a perspective view showing a lower chassis of the optical system unit of the liquid crystal projector according to the present invention. The lower chassis plate 8b is made of a metal plate. The periphery of the lower chassis plate 8b is processed by a bending work, a drawing work, and so forth so that the lower chassis plate 8b is formed in a box shape. The lower chassis plate 8b forms part mounting holes 8h. Fixing frames which fix the dichroic mirrors, reflection mirrors, and so forth are mounted and fixed to these holes. Since the lower chassis plate 8b is made of a metal plate, its production cost is low. In addition, by slightly modifying the shape of the metal mold of the lower chassis plate 8b, the design of the lower chassis plate 8b can be changed wholly or partially. Moreover, since the lower chassis plate 8b is constructed in the box shape by a bending work, a drawing work, and so forth, the strength thereof is maintained. Thus, when the lower chassis plate 8b is fixed to an outer case of a liquid crystal video projector with screws, even if an excessive force is applied to the lower chassis plate 8b, the positions and angles of the

part mounting holes thereof would not deviate.

Thus, deviations of positions and angles of the reflection mirrors, which have been known as a cause of unevenness of colors and deviation of pixels, can be solved and thereby more beautiful pictures can be projected.

In a liquid crystal video projector shown in Fig. 12, light of a white light source is separated into rays of three colors of red, green, and blue with separating dichroic mirrors 2 and 3a. The rays of separated colors enter liquid crystal light bulbs 7b, 7a, and 7c. Thereafter, the rays of separated colors are mixed by mixing dichroic mirrors 3b and 5. Next, the mixed rays are projected onto a screen with a projection lens 9.

In this case, if any liquid crystal light bulb has a point defect, the relevant color of red, green, and blue is always lit or put out. Thus, the color of this portion changes. This point defect is not remarkable in the periphery of the screen, but in the center. In addition, the point defect of blue color whose relative visibility is low is not remarkable, while that of green color whose relative visibility is high is remarkable. Thus, the liquid crystal light bulb for green requires higher specifications than that for blue. In other words, if the high specifications were maintained, the yield of the liquid crystal light bulb for green would be lower than that of the liquid crystal light bulb for blue.

To prevent this disadvantage, when the liquid crystal light bulb for green is produced in the same construction as that for blue, that is, both the liquid crystal light bulbs have compatibility each other, the better one can be used for green so as to decrease remarkable green point defects. In a quantitative production stage, liquid crystal light bulbs which are not suitable for green can be sometimes used for those for blue. Thus, when the liquid crystal light bulbs for green are used for those for blue, the yield thereof can be improved. In addition, since the number of types of liquid crystal light bulbs to be designed and produced is reduced from three to two, the cost thereof can be decreased.

In a liquid crystal video projector shown in Fig. 13, light of a white light source is separated into rays of three colors of red, green, and blue with separating dichroic mirrors 2 and 2a. The rays of separated colors enter liquid crystal light bulbs 7b, 7a, and 7c. Thereafter, the rays of separated colors are mixed by mixing dichroic mirrors 3b and 5. The mixed rays are projected onto a screen with a projection lens 9. However, the liquid crystal light bulbs are susceptible to heat. When these liquid crystal light bulbs are exposed to strong light, the temperature thereof rises and thereby accelerating the deterioration thereof. To solve this problem, a cooling fan 66 mounted in the vicinity of the liquid

crystal light bulbs is rotated so as to generate wind. This wind cools down the liquid crystal light bulbs so as to prevent them from deteriorating.

In this embodiment, the red color type liquid crystal light bulb 7b is disposed midway between the green color type liquid crystal light bulb 7a and the red color type liquid crystal light bulb 7c. Below the red color type liquid crystal light bulb 7c, the cooling fan 66 is disposed. The wind produced by the cooling fan 66 cools down the three liquid crystal light bulbs. When the cooling fan 66 is rotated, it allows wind to satisfactorily blow the blue and green color type liquid crystal light bulbs 7c and 7a disposed outside of the red color type liquid crystal light bulb 7b.

The cooling fan 66 according to this embodiment is of a blade type. When the cooling fan 66 is rotated, the wind force in the periphery thereof is stronger than that in the center thereof. The wavelength of rays of light which enter each liquid crystal light bulb differs each other. The energy of rays of blue region which enters the blue color type liquid crystal light bulb is higher than that of the green and red regions. Thus, since the temperature of the blue color type liquid crystal light bulb rises most, the necessity of cooling this bulb is highest. In contrast, since the energy of rays which enter the red color type liquid crystal light bulb is least and the temperature of this bulb does not highly rise, the necessity of cooling this bulb is comparatively low. In addition, since rays which enter each liquid crystal light bulb have been passed through an infrared ray cutting filter after emitted from the light source, infrared rays do not enter each liquid crystal light bulb.

Thus, as described in the above-mentioned embodiment, the cooling fan 66 is disposed below the red color type liquid crystal light bulb 7b so that wind produced by the cooling fan 66 satisfactorily blows the blue and red color type liquid crystal light bulbs. In other words, the blue color type liquid crystal light bulb which is highly heated by the rays with high energy is disposed at the peripheral portion of the cooling fan where the wind force is strong and the red color type liquid crystal light bulb which is less heated by the rays with low energy is disposed at the center portion of the cooling fan where the wind force is weak. Consequently, each liquid crystal light bulb can be effectively cooled down without cooling loss. In addition, with one fan, the plurality of liquid crystal light bulbs can be cooled down. In addition to reducing the cost of the product, the weight and size thereof can be decreased.

In this embodiment, an image produced by entering rays of red region separated by the separating dichroic mirrors 2 and 3a into the liquid crystal light bulb 7a (hereinafter this image is re-

ferred to as a red image) and an image produced by entering rays of green region separated likewise (hereinafter this image is referred to as a green image) are mixed by the dichroic mirror 3b. Thereafter, the mixed image and an image produced by entering rays of blue region into the liquid crystal light bulb 7c (hereinafter this image is referred to as a blue image) are mixed by the dichroic mirror 5. Thus, a mixed image with three colors of red, green, and blue can be obtained.

In the above-mentioned embodiment, by decreasing the thickness of the red color mixing dichroic mirror 3b, the astigmatism of the green image which passes through this mirror 3b is decreased. However, when the thickness of the dichroic mirror is decreased, the surface accuracy of the red mixing dichroic mirror 3b deteriorates and thereby lowering the accuracy of the reflection. Thus, it is supposed that the resolution of the red image being reflected degrades. However, since the distance between the red mixing dichroic mirror 3b and the red color type liquid crystal light bulb 7b is short, the degradation of the surface accuracy of the red mixing dichroic mirror does not almost affect the image quality. Moreover, in this embodiment, by increasing the thickness of the yellow mixing dichroic mirror 5, the surface accuracy is maintained and thereby the resolution of the image mixed by the red mixing dichroic mirror 3b is maintained. However, when the thickness of the yellow mixing dichroic mirror 5 is increased, the astigmatism of the blue image transmitted in the yellow mixing dichroic mirror 5 becomes large. Nevertheless, since the relative visibility of the blue image is lower than that of the green and red images, it is not remarkable.

Thus, in the embodiment shown in Fig. 12, since the green color type liquid crystal light bulb 7a and the blue color type liquid crystal light bulb 7c are interchangeably used, point defects of the green image with high relative visibility can be decreased. A liquid crystal light bulb which is not suitable for the green color liquid crystal light bulb 7a can be sometimes used for one for blue. Thus, the yield can be improved. Conventionally, three types of liquid crystal light bulbs have been designed and produced. However, according to this embodiment, the number of types of liquid crystal light bulbs can be reduced from three to two. Thus, the cost reduction can be accomplished.

In the embodiment shown in Fig. 13, the red color type liquid crystal light bulb 7b is disposed midway between the green color type liquid crystal light bulb 7a and the blue color type liquid crystal light bulb 7c. The cooling fan 66 which allows wind to satisfactorily blow the green and blue type color liquid crystal light bulbs 7a and 7b is disposed below the red color type liquid crystal light bulb 7b.

5 Thus, the blue color type liquid crystal light bulb which is heated most can be effectively cooled down. Consequently, without cooling losses, the single fan can cool down the plurality of liquid crystal light bulbs. Therefore, in addition to reducing the production cost, the weight and size thereof can be decreased.

10 Moreover, in the embodiment shown in Fig. 12, by decreasing the thickness of the red color mixing dichroic mirror 3b, the astigmatism of a green image whose relative visibility is high can be decreased. By increasing the thickness of the yellow color mixing dichroic mirror, the surface accuracy thereof can be improved. Thus, the image mixed by the red color mixing dichroic mirror 5 can be precisely reflected.

15 Figs. 14 to 56 show practical examples of the overall construction including a cooling unit of the liquid crystal projector of the present invention. Fig. 14 is a schematic assembly plan view seen from the top of the liquid crystal projector.

20 The liquid crystal projector of the present invention has a case 70 which is nearly in a rectangular parallelepiped shape. The case 70 accommodates all parts functionally separated as units. As shown in Figs. 17 to 19, the case 70 comprises a lower case 72 and an upper case 71 which can be separated at a separation line 73.

25 At front symmetrical positions of the bottom of the lower case 72, a pair of threaded adjustment fits 74 for adjusting the vertical position of a projected picture are provided. At a position below an optical unit 75 (which will be described later), an air intake slit portion 76 is formed. At rear symmetrical positions of the lower case 72, a pair of fixing fits 77 and 77 are disposed.

30 A window 78 of the projection lens is formed at a position slightly left of the center of the case 70. By sliding a cover plate 78 sidewardly, the window 79 is open. Since the cover plate 79 is bent in an arc shape, it is slid in the path of the arc.

35 At a right position of the rear of the case 70, an interface board frame unit 80 for connecting each interface is attached from the top. At a left position of the rear of the case 70, an air exhaust fan cover 81 is attached from the top. In the center of the air exhaust fan cover 81, an air exhaust opening 82 is formed. As shown in Fig. 19, at a lower center position of the rear of the case 70, a power receptacle 83 is disposed.

40 At a left position of the rear of the case 70, a lamp house cover 85 for accessing an inner housing 154 is disposed.

45 At a position nearly left of the center of the top of the upper case 71, a speaker hole portion 86 for conveying sound generated by a speaker is formed. On the speaker hole portion 86, a speaker cover 87 made of a punched plate having small

holes is disposed. At a front position of the top of the upper case 71, an operation panel 88 on which the user performs for example image, sound, and autofocus adjustment operations is disposed. At a rear position of the center of the top of the upper case 71, a power switch button 89 is disposed.

A base plate 90 is detachably mounted on the lower case 72 with screws.

On the base plate 90, an optical unit 98 (see Fig. 28) where a lamp housing unit 91 and a projection lens unit 92 are assembled in a light guide unit 102 is disposed in such a way that the main optical path is in an L shape when viewed from the top thereof (see Fig. 14). In addition, the projection lens unit 9 faces the window 78 in the front of the case 70. Moreover, the access direction of an inner housing 154 of the lamp housing unit 91 faces the lamp housing cover 85 on the left of the case 70.

A power unit 95 is disposed in the front of the lamp housing unit 91 and on the air intake side. A lamp stabilizing unit 96 is disposed on the left of the projection lens unit 9. A video board unit 97 is disposed outside the optical unit 75. The lamp housing unit 91, the power unit 95, the stabilizing unit 96, the video board unit 97, and the optical unit 98 are separately and detachably mounted on the base plate 90.

The power unit 95 and the lamp stabilizing unit 96 are accommodated in a shield case having a plurality of holes for drawing and exhausting air. The speaker 99 is fixed to the power unit 95 through the shield case.

A drive board unit 100 has a liquid crystal drive circuit, a microcomputer built-in system control circuit, and so forth. The drive board unit 100 is disposed at the top of the optical unit 75. The drive board unit 100 has board holes 101 for routing cables for the liquid crystal light panels and air flow paths thereof. These board holes 101 are formed over the respective liquid crystal light bulbs. These board holes 101 allow air to flow to the top of the drive board unit 100.

The air intake fan 66, which is an axial flow fan, is mounted on the base plate 90 below the light guide unit 102. An integrally formed inlet air regulating plate 105 disposed midway between the air intake fan 66 and the light guide unit 102 allows fresh air drawn through the air intake slit portion 76 and a dust protecting filter 104 disposed on the bottom to branch into at least three flow routes toward the liquid crystal light bulbs and into a plurality of flow paths in the direction perpendicular to the air blow opening.

The optical unit 98 is the above-mentioned optical means. Hereinafter, the above-mentioned upper chassis plate 8a is referred to as an upper light guide 121 and the lower chassis plate 8b as a

lower light guide 126. Then, these light guides 121 and 126 will be described in detail.

As shown in Fig. 22, the air intake regulating plate 105 is connected to a guide hole 107 of the lower light guide 126. Thereafter, by screwing the fixing holes 108, the air intake regulating plate 105 is fixed to the lower light guide. The air intake fan 103 is disposed at a position perpendicular to the three liquid crystal light bulbs 7c (7a, and 7b), which are disposed in a crank shape. In addition, these three liquid crystal light bulbs 7a, 7b, and 7c are disposed in a projection area with the air blow diameter of the air intake fan 66. As the result, the distance between the air blow opening 111 and each of liquid crystal light bulbs 7a, 7b, and 7c becomes short. In addition, the temperatures of the liquid crystal light bulbs 7a, 7b, and 7c and the polarizing plates 112 can be decreased.

A second embodiment of the air intake regulating plate 105 has basically a cylindrical shape as shown in Fig. 50. A third embodiment of the air intake regulating plate has a construction where two curved branching walls and a straight wall are added to the construction of the first embodiment, the branching walls being connected inwardly from the periphery of the air intake regulating plate to the straight wall which is disposed in parallel with the surface of the liquid crystal light bulb. The axial flow fan causes wind to blow in an inclined direction which is the same as the rotating direction of blades. Fig. 56(a) shows a result of air speed data of the axial flow fan. From this figure, it is known that when no obstacles (such as net and filter) are present in the air intake side of the axial flow fan, although the center portion of iso-speed curve a is low, the curve is extended toward the front of the blades. When there are obstacles, as shown in Fig. 56(b), the overall speed of the axial flow fan decreases and the curve a is extended to in the vicinity of the air blow opening. Thus, the wind blows outward. In the second embodiment, the iso-speed curve shown in Fig. 56(c) is obtained. The speed and direction of wind of the second embodiment as shown in Fig. 56(c) are superior to those of the related art as shown in Fig. 56(b). The iso-speed curve of the third embodiment is shown in Fig. 56(d). In the third embodiment, wind also blows from the center portion of the axial flow fan to the air blow side. As shown in Fig. 22, the first embodiment of the air intake regulating plate 105 is an improvement of the third embodiment. In the first embodiment, so as to easily inject and mold plastics, air blow openings 116, 117, and 118 facing three liquid crystal panel blocks 115 are formed below these blocks 115 on an upper surface 66a of a cylindrical member 66. A plurality of branch walls 119 made of curved and straight portions are disposed so that air flows through the liquid crystal

light bulb 7c (7a, and 7b) equally upwardly along the space of the polarizing plates 112. In addition, to activate the air flow of the entire flow paths in the case, a plurality of air blow openings 120 are formed on the side of the cylindrical member.

In Fig. 14, the optical unit 75 is a block for separating and mixing light of a light source. Reference numeral 121 an upper light guide which is made of a metal plate and is in a box shape. A light entrance opening 122 from which light enters and a light emit opening 123 to which light is emitted are open. Reference numeral 124 is an air blow opening of three air paths formed on the top 125 of the upper light guide 121. Reference numeral 126 is a lower light guide which is nearly in a box shape. The upper light guide 121 accommodates optical parts in such a way that the upper light guide 121 covers the lower light guide 126. Column members are disposed midway between the upper light guide 121 and the lower light guide 126. In addition, the upper light guide 121 and the lower light guide 126 are fixed with screws. As a result, the strength of the optical unit 75 becomes high. Reference numeral 127 is a prepolarizer block where a prepolarizer 128 made of a plurality of glass plates arranged in a V shape is clamped with a glass fixing plate 129, a support rubber 130, and a glass support plate 131. A UV and IR filter portion 132 is adhered to the glass support plate 131 with a double-sided adhesive tape. The prepolarizer block 127 is mounted at the position of the light entrance opening 122 of the optical unit 75. In this blocked construction, the length of the optical paths in the optical unit 75 is shortened and the shock resistance thereof is improved.

Next, optical parts accommodated in the optical unit will be described. The optical unit has three blocks, each of which contains the prepolarizer 128, the UV and IR filter portion 132, and the liquid crystal light bulb 110. The polarizing plates 112 are disposed before and after each liquid crystal light bulb. Thus, a total of six polarizing plates 112 are disposed in the three blocks. Reference numerals 4a and 4b are mirrors. Reference numerals 2, 3a, 3b, and 5 are dichroic mirrors. Reference numeral 135 is a condenser lens. These optical parts are fixed to plate shape fixing members. These fixing members are fixed to the inside of the optical unit 75. As described above, the liquid crystal light bulbs 7a, 7b, and 7c, and the polarizing plates 112 are grouped into three liquid crystal light bulb blocks 115, each of which has an adjustment mechanism.

The projection lens unit 9 is fixed in accordance with the light emit opening 136 of the lower light guide 126.

Figs. 23 to 26 show the construction of the lower light guide 126. Fig. 23 is a plan view of the

lower light guide 126. Fig. 24 is a rear view of the lower light guide 126. Fig. 25 is a side view of the lower light guide 126. Fig. 26 is a front view of the lower light guide 126. Reference numeral 137 is a upper air blow opening according to the air flow path of the air blow opening of the inlet air regulating plate 105. Reference numeral 138 is an air blow opening. This air blow opening 138 contributes to reducing the weight of the lower light guide 126. Reference numeral 139 is an air flow path guide. As shown in Fig. 27, the air flow path guide 139 is a wall which is bent by 90° so as to guide a cooling air to the liquid crystal light bulb 7c, (7a, and 7b) and the polarizing plates 112 through the air intake opening 140.

Reference numeral 141 is an exhaust fan fixing plate. As shown in Figs. 28, 29, 30, and 36, the exhaust fan fixing plate 141 has skirt-shaped air inlet guides 142 on the top, the right, and the left thereof so as to suppress drawing air from the side of the air intake opening of the exhaust fan 143 and to preferentially cool down heated members on the entire surface of the air intake opening in front of the air blow opening of the exhaust fan 143.

As shown in Figs. 28 and 34, a space 144 is formed in the vicinity of the lamp. By disposing the lamp in the vicinity of the air intake opening of the exhaust fan 143, the lamp and the highly heated portion in the vicinity thereof can be directly and effectively cooled down.

In the conventional liquid crystal projectors, there is a problem where dust and rubbish are attracted from the opening in the front of the projection lens 9. To solve this problem, a side air blow opening of the air intake regulating plate 105 is rotated clockwise. The air from the rotating air blow opening strikes against the upper wall on the right of the lower light guide 126 and thereby the wind is directed toward the window of the projection lens. In addition, a branching plate 145 shown in Fig. 14 is disposed so as to prevent influence of the attracting force of the exhaust fan 143. Thus, the amount of blow air of the front air exhaust opening becomes weak. As a result, dust and rubbish are not attracted. The branching plate 145 is made of a thin plastic plate. The branching plate 145 is nearly in a rectangular shape. Part of the plate 145 is bent by 90° and adhered to flat surfaces of the base plate 90 and the lamp stabilizer 96 with a double-sided adhesive tape.

Reference numeral 146 is a lamp fan block. The lamp fan block 146 is formed by winding a metal plate around the circumference of a lamp fan 147. One side of the lamp fan block 146 is screwed to a lamp fan fixing plate 149 which forms an air blow opening rotated by 90° from an air blow opening of the lamp fan 147. On a side of a window frame 150 in the front of the air blow

opening of the lamp fan 147, the lamp fan fixing plate 149 is screwed so as to form the lamp fan block 146. The lamp fan block 146 is fixed on a side of the light entrance opening 122 of the upper light guide. The window frame 150 prevents light of the lamp from leaking out by using a surface of a front portion 151 and an 90° bend portion 152 as shown in Fig. 33. In addition, the window frame 150 allows air of the lamp fan 147 to pass through from a window frame hole 153.

Next, an inner housing block 154 of the lamp housing unit 91 will be described. As shown in Figs. 34 to 47, reference numeral 1 is a lamp as a light source. In the lamp 1, a lighting tube 156 is fixed to a reflector 157. The lamp 1 is positioned and fixed to an L-shaped lamp fixing plate 158 with a lamp spring 159. A lamp male connector 160 is positioned and screwed to an L-shaped lower cut portion of the lamp fixing plate 158. The lamp fixing plate 158 is surrounded by a lamp inner housing member 161 and screwed to the lamp fixing plate 158. The inner housing member 161 has a handle 162. In the rear of the lamp 1, a rear electrode plate 163 and a side electrode plate are disposed. Both the electrodes and the lamp male connector 160 are connected with electric wires 164. These electric wires 164 have a high heat resistance. In addition to the electric wires, respective electric wire connecting portions of the lamp male connector 160 are coated with highly insulated shrinkable tubes 165. On a side of the inner housing member 161, a vent hole portion 166 for cooling is disposed. In the front of the lamp lighting tube 156, a heat insulating film 167 is coated. In the figure, reference numeral 168 is a control portion. Reference numeral 169 is a hole for providing an insulating distance. Reference numeral 170 is a fixing portion of the lamp inner housing block 154. Reference numeral 171 is a grille portion for providing an insulation distance. Reference numeral 172 is an E ring with which the lamp can be replaced without removing screws from the inner housing. Reference numeral 173 is a slide guide portion. Reference numeral 174 is an upper-lower positioning portion. Reference numeral 175 is a vertical positioning portion. Reference numeral 176 is a left-right positioning portion. Reference 177 is an opening portion.

The vent hole portion 166 is formed at a pitch different from those of the vent hole of the outer housing member 178 and grille windows 180 so that light does not leak out to the outside.

Next, a lamp outer housing block 181 of the lamp housing unit 91 will be described.

The front of the outer housing member 178 is an entrance opening of the inner housing block 154. In the front, there are screw holes for fixing the inner housing and two fixing tables 182 where

three portions of the lamp outer housing block 181 are cut and raised. On the left side of the lamp outer housing block 181, there are grille windows 180 for downward ventilation and vent holes 179.

- 5 On the right side of the lamp outer housing block 181, there are grille windows 180 for upward ventilation and vent holes 179. At the top of the lamp outer housing block 181, there are a grille portion 178a for providing an insulation distance, left and right positioning holes 183 of the lamp fixing plate 158, screw holes 184 for fixing an overheat protection safety switch, and a screw hole 185 for fixing a thermistor. In the rear of the lamp outer housing block 181, there are a vertical air flow control portion 186 and a horizontal air flow control portion 187 for allowing wind to blow the surface of the lamp lighting tube 156 and the most hottest portion of the heat insulation film. These portions 186 and 187 are formed by cutting and rising the lamp outer housing block 181. In addition, at a center position of the rear of the lamp outer housing block 181, a light emit opening 188 is formed. At a lower position of the rear of the lamp outer housing block 181, a connector window 189 is formed. In the rear of the lamp outer housing block 181, a rear member 190 with high vertical accuracy and upper-lower positioning portions 191 are formed. Moreover, in the rear of the lamp outer housing block 181, there are fixing holes 192 for fixing the lamp outer housing block 181 to the base plate 90 and positioning holes 193 thereof.

Reference numeral 194 is a lamp connector plate for connecting a lamp female connector 196 to a connector fixing portion 195 through a connector bush 197.

There is a space between the connector bush 197 and the connector fixing hole 198. This space absorbs the axial deviation of the connector. A lamp connector plate upper member 199 insulates the connector from light. In addition, the upper member 199 shields the connector from EMI. Reference numeral 200 is a ground terminal fixing portion. The lamp female connector 196 has a guide slope for smooth connection.

- 45 When the inner housing block 154 is inserted into the outer housing 181, the vertical positioning portions 175 of the inner housing 154 are contacted to the rear member 190 which is the reference surface of the outer housing 154. In addition, the upper-lower and left-right positioning portions 174 and 176 are contacted in positions. As a result, the inner housing block 154 is correctly positioned.
- 50

Then, a second embodiment of the case 70 will be described with reference to Figs. 52 and 53.

- 55 Reference numeral 201 is an exhaust air drawing protection wall. When the liquid crystal projector is installed in such a way that the rear of the case of the projector contacts a wall, this protection

wall 201 prevents the air intake opening from drawing exhausted warm air through the space between a case bottom 202 and the floor.

Next, a third embodiment of the case 70 will be described with reference to Figs. 54 and 55.

In this embodiment, the strength of the exhaust air drawing protection wall 201 of the second embodiment is improved so that it can have the function of a foot.

As described above, fresh air drawn by the air intake fan 105 cools down the liquid crystal light bulbs 7a, 7b, and 7c. Thereafter, the air flows from the opening portion 101 of the drive board unit 100 upwardly. Next, the air is merged with air coming from the side openings 120 of the air intake regulating plate 105 in the vertical direction and then cools down the lamp stabilizer unit 96 and the power unit 95. Thereafter, the air cools down the lamp 1. Finally, the air is exhausted to the outside by the lamp fan 147 and the air exhaust fan 143.

In the above-mentioned construction, the optical unit, which comprises the lamp housing unit, the liquid crystal light bulbs, the mirrors, the dichroic mirrors, and the projection lens, the air intake fan, the lamp fan, the exhaust fan, and so forth are compactly accommodated nearly in a rectangular parallelepiped case so that an image mixed by at least three liquid crystal light bulbs for forming color images is projected as a picture onto a screen with a projection lens. In addition, with the air intake regulating plate and the air branching plates, the air flow paths can be branched and enlarged. Thus, the operability, durability, maintainability, and environmental properties are improved.

Figs. 57 and 58 show a cooling means of the lighting unit of the liquid crystal projector. Fig. 57 is a view showing the construction of the cooling means. The lamp 1 comprising a metal halide lamp 156 and a lamp reflector 157 is fixed to a lamp fixing plate 158 and accommodated in a lamp house 207. A rear sealed portion 208 of the metal halide lamp 156 is inserted into a lamp fixing portion 209 of the lamp reflector 157 and then fixed with cement or the like. By connecting a front electrode plate 210 and a rear electrode plate 163 of the metal halide lamp to the lamp stabilizer 96 disposed outside the lamp unit, the metal halide lamp 156 can be lit. As the cooling means, the air exhaust fan 143 which is an axial flow fan and has blades with outer diameter equal to or larger than the diameter of the opening portion of the lamp reflector 157 is disposed near the lamp house 207. Thus, the air exhaust fan 143 draws air through the inside of the lamp house 207. On the sides of the lamp house 207, there are air intake and exhaust holes for cooling down the lamp 1. Thus, air flows in the directions of arrow marks of the figure in the

5 lamp house 207. In addition, at a position close to the lamp reflector opening portion 214, the lamp fan 147 which is smaller than the diameter of the lamp reflector opening portion 214 is disposed.

When an axial flow fan is used for the lamp fan 147, the wind is widened toward the air blow direction. In addition, since the wind is twisted in the rotating direction of the fan, the wind also flows to the region surrounded by the lamp reflector 157.

10 Fig. 58 is a side view of the cooling means. In the front of the air blow side of the lamp fan 147, an air regulating plate 216 is disposed. The air regulating plate 216 can accurately guide cold air directly to the surfaces of the lighting tube 156 and the front sealed portion 156a in the direction of the arrow mark of the figure.

15 It should be noted that the lamp fan 147 can be a scirocco fan or a cross flow fan. In addition, the lamp fan 147 can be installed with an angle. Moreover, the blowing direction of the lamp fan 147 can be changed in the range of the conventional blowing direction $\pm 90^\circ$.

20 Further, the regulating plate 216 can be disposed in the lamp house 147 or midway between the lamp house 207 and the lamp fan 147.

25 In the above mentioned construction, after the metal halide lamp 156 is discharged and lit, the air exhaust fan 213 cools down the entire lamp 1. In addition, the lamp fan 147 and the regulating plate 216 produce air flows on the surfaces and peripheries of the lighting tube 156 and the front sealed portion 156a, thereby improving the cooling effect. In other words, the lamp fan 147 draws fresh air and causes wind to blow the lamp reflector opening portion 214. Thus, an air flow can be positively produced in the region surrounded by the reflection surface of the lamp reflector 157.

30 Thus, by decreasing the surface temperature of the quartz glass constructing the lighting tube 156 to 900°C or below, the phenomenon where only the upper portion becomes opaque can be prevented. As a result, the differences of brightness and temperatures at upper and lower portions of the lighting tube 156 can be reduced. In addition, when the temperature of the front sealed portion 156a is decreased to 300°C or below, the air insulation can be maintained for a long time. Thus, the life of the lighting unit can be prolonged.

35 Thus, as the above-mentioned cooling means, by disposing another lamp fan at a position adjacent to the reflector opening portion, air flows effectively take place on the surface of the lighting tube and in the front sealed portion in the region surrounded by the reflection surface of the lamp reflector. Therefore, the surface temperature of the quartz glass can be cooled down to a required temperature or below. As a result, the phenomenon where part of quartz glass becomes opaque does

not take place. Consequently, the optical properties such as brightness and color temperatures can be stabilized. In addition, when the temperature of the front sealed portion is decreased to the required temperature or below, the air insulation of the metal halide lamp can be maintained for a long time and thereby the life thereof can be prolonged. When this lighting unit is used in the liquid crystal color projector, projected pictures which are free of uneven intensity of illumination and uneven colors can be accomplished. Moreover, in comparison with the related art, the metal halide lamp with a long life can be accomplished.

Industrial Utilization

The present invention is suitable for a projection type liquid crystal video projector which is small in size and light in weight, free of uneven colors and deviation of pixels, and has high brightness and high magnification.

Claims

1. A projection type liquid crystal projector, comprising,

optical means, comprising a light source, a plurality of dichroic mirrors for separating white light emitted by said light source into blue, green, and red colors of rays, respective liquid crystal light bulbs for forming images of said blue, green, and red colors of rays so as to form optical paths, and

a projection lens,

wherein said optical means is characterized in that at a center portion of a chassis made of members with rigidity, a first color type bulb of said liquid crystal light bulbs for forming said red, green, and red colors of rays, second and third color type bulbs of said liquid crystal light bulbs being disposed at positions point-symmetrical to said first color bulb, and

wherein said projection type liquid crystal projector further comprises an adjustment mechanism for mutually matching pixels of said second and third color bulbs with those of said first color bulb.

2. The projection type liquid crystal projector as set forth in claim 1, wherein said adjustment mechanism is adapted to adjust said pixels in horizontal, vertical, and rotational directions.

3. The projection type liquid crystal projector as set forth in claim 1, wherein said adjustment mechanism is adapted to adjust the focal point of said projection lens and to adjust the positions of said liquid crystal light bulbs so that

they are placed perpendicular to their optical axis.

4. The projection type liquid crystal projector as set forth in claim 1, wherein said adjustment mechanism is adapted to adjust said optical means only from the top thereof or at most from three sides thereof.
5. The projection type liquid crystal projector as set forth in claim 1, wherein said projection type liquid crystal projector is adapted to be free of adjustment of the position of said first color bulb or to perform only an adjustment for placing said first color bulb in a position perpendicular to an optical axis thereof.
6. The projection type liquid crystal projector as set forth in claim 1, wherein said adjustment mechanism is adapted to perform an adjustment for placing said first color bulb to a position close to the focal position of said projection lens.
7. A projection type liquid crystal projector, comprising,
an adjustment mechanism having at least two mutually slidable members,
wherein said slidable members have respective notches at opposed positions thereof.
8. A projection type liquid crystal projector, comprising,
a lower chassis plate,
reflection mirrors fixed to said lower chassis plate, and
liquid crystal light bulbs,
wherein said lower chassis plate is made of a metal plate, the periphery of said lower chassis plate being processed by bending work or drawing work.
9. A projection type liquid crystal projector, comprising,
a white lamp,
dichroic mirrors for separating light of said white lamp into rays of three colors of red, green, and blue, and
liquid crystal light bulbs for transmitting said rays of three colors and for forming images,
wherein a blue color type bulb for forming a blue image of said liquid crystal light bulbs has the same construction as a green color type bulb thereof so as to have compatibility each other.
10. A projection type liquid crystal projector, com-

prising,

dichroic mirrors for separating light into rays of three colors of red, green, and blue, and

liquid crystal light bulbs for forming respective images,

wherein a red color type liquid crystal light bulb for forming a red image of said liquid crystal light bulbs is disposed midway between a blue color type liquid crystal light bulb for forming a blue image and a green color type liquid crystal light bulb for forming a green image, and

wherein a cooling fan is disposed below said red color type liquid crystal light bulb.

11. A projection type liquid crystal projector, comprising,

dichroic mirrors for separating light into rays of three colors, and

liquid crystal light bulbs for forming images; and dichroic mirrors for mixing rays of said three colors,

wherein the thickness of a first dichroic mirror for mixing rays of two colors is thinner than that of a second dichroic mirror for mixing said rays of two colors mixed by said first dichroic mirror with the remaining color.

12. A projection type liquid crystal projector, comprising,

a case nearly in a rectangular parallelepiped shape,

a base plate disposed in said case,

a lamp housing unit having a projection light source,

an optical unit, comprising image forming liquid crystal light bulbs, light mixing and separating mirrors, dichroic mirrors, prepolarizers, and a projection lens, said lamp housing unit and said optical unit being disposed on said base plate so that a main optical path and the outer shape become a plane L shape, said projection lens facing a window of the front of said case, one end of said lamp housing unit facing a window of a lamp house cover on a side of said case and the other an air exhaust opening in the rear of said case,

a power unit and a lamp stabilizer disposed at a space surrounded by the plane L shape portion, the front and the side of said case,

an air intake regulating plate disposed below said liquid crystal light bulbs,

an air intake fan disposed below said air intake regulating plate,

a video board disposed between a side of said case and said light guide unit,

5 a liquid crystal drive board unit disposed midway between the top of said case and the top of said light guide unit,

an air exhaust fan disposed midway between said air exhaust opening in the rear of said case and said lamp housing unit, and

10 a lamp fan disposed in the front of a light emit surface of said lamp housing unit.

13. A projection type liquid crystal projector having a lamp fan block for cooling down a lamp lighting tube, said lamp fan block being characterized in that a barrier in a box shape lacking one side is formed in the front of an air blow opening of an axial flow fan so as to change the air blow direction by 90°.

14. A projection type liquid crystal projector having a lamp fan disposed on a side of a light guide and in the front of a light emitting opening of a lamp housing unit, said lamp fan being fixed to the side of said light guide.

15. A projection type liquid crystal projector having an air intake fan, said air intake fan being disposed in such a way that said air intake fan is placed in a position perpendicular to the surfaces of three liquid crystal light bulbs disposed in a crank shape, said three liquid crystal light bulbs being placed in an area with the nearly same diameter as the diameter of an air blow opening of said air intake fan.

16. The projection type liquid crystal projector as set forth in claim 12, wherein said air intake regulating plate having a cylindrical shape with the same diameter as the outer diameter of the air blow opening of said air intake fan.

17. The projection type liquid crystal projector as set forth in claim 12, wherein said air intake regulating plate is disposed between an air intake fan and a liquid crystal light bulb block, said air intake regulating plate having a cylindrical shape and a streamline shape wall in parallel with the front of said liquid crystal light bulbs, said air intake regulating plate being adapted to branch an air flow path to said three liquid crystal light bulb blocks.

18. The projection type liquid crystal projector as set forth in claim 12, wherein an air intake regulating plate integrally formed is disposed, said air intake regulating plate having at least three flow path branches in the same direction of the blowing opening of a fan and at least one flow path branch in the direction perpendicular to the air blow opening of said fan.

19. The projection type liquid crystal projector as set forth in claim 12, wherein said case has one major air intake opening and two air exhaust openings.

5

20. The projection type liquid crystal projector as set forth in claim 12, wherein said case has one major air intake opening and two air exhaust openings, a branch plate being disposed midway between said two air exhaust openings.

10

21. The projection type liquid crystal projector as set forth in claim 12, wherein an air intake guide for drawing air from a plurality of members is disposed at an air intake opening of said exhaust fan.

15

22. The projection type liquid crystal projector as set forth in claim 12, wherein an air exhaust path is disposed midway between said lamp housing unit and said light guide unit in the direction perpendicular to the optical axis thereof.

20

25

23. The projection type liquid crystal projector as set forth in claim 12, wherein a visible light transmissive type UV and IR filter portion is disposed midway between said prepolarizer and said optical separating mirror, said filter portion being accommodated in said light guide unit.

30

24. The projection type liquid crystal projector as set forth in claim 12, wherein an exhaust air drawing protection wall is disposed between an air intake flow path of said air intake opening and an exhaust air flow path of said air exhaust opening.

35

40

25. The projection type liquid crystal projector as set forth in claim 24, wherein said exhaust air drawing protection wall is integrally formed with a feet.

45

50

55

26. A projection type liquid crystal projector having a lighting unit, said lighting unit comprising, a light source consisting of a metal halide lamp and a lamp reflector, wherein a lamp house is adapted to accommodate said light source and cooling means for cooling down said light source, and wherein said cooling means comprises a fan disposed adjacent to said lamp house and a lamp fan disposed adjacent to an opening portion of said lamp reflector.

27. A projection type liquid crystal projector having a lighting unit, said lighting unit comprising, a

light source consisting of a metal halide lamp and a lamp reflector, wherein a lamp house is adapted to accommodate said light source and cooling means for cooling down said light source, wherein said cooling means comprises a fan disposed adjacent to said lamp house and a lamp fan disposed adjacent to an opening portion of said lamp reflector, and wherein a regulating plate is disposed in a position opposed to said lamp fan.

* Special categories of cited documents: ⁸⁾

"A" document defining the general state of the art which is not considered to be of particular relevance

"T" later document published after the International filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"E" earlier document but published on or after the International filing date

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"O" document referring to an oral disclosure, use, exhibition or other means

"Z" document member of the same patent family

"P" document published prior to the International filing date but later than the priority date claimed

IV. CERTIFICATION

Date of the Actual Completion of the International Search	Date of Mailing of this International Search Report
March 5, 1992 (05. 03. 92)	March 24, 1992 (24. 03. 92)
International Searching Authority: Japanese Patent Office	Signature of Authorized Officer

V. OBSERVATIONS WHERE CERTAIN CLAIMS WERE FOUND UNSEARCHABLE ¹

This international search report has not been established in respect of certain claims under Article 17(2) (a) for the following reasons:

1. Claim numbers because they relate to subject matter not required to be searched by this Authority, namely:

2. Claim numbers because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. Claim numbers because they are dependent claims and are not drafted in accordance with the second and third sentences of PCT Rule 5.4(a).

VI. OBSERVATIONS WHERE UNITY OF INVENTION IS LACKING ²

This International Searching Authority found multiple inventions in this international application as follows:

1. As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims of the international application.

2. As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims of the international application for which fees were paid, specifically claims:

3. No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claim numbers:

4. As all searchable claims could be searched without effort justifying an additional fee, the International Searching Authority did not invite payment of any additional fee.

Remark on Protest

- The additional search fees were accompanied by applicant's protest.
- No protest accompanied the payment of additional search fees.
